**Method and nucleic acids for the improved treatment of breast cell proliferative disorders**

**Field of the Invention**

The levels of observation that have been studied by the methodological developments of recent years in molecular biology, are the genes themselves, the translation of these genes into RNA, and the resulting proteins. The question of which gene is switched on at which point in the course of the development of an individual, and how the activation and inhibition of specific genes in specific cells and tissues are controlled is correlatable to the degree and character of the methylation of the genes or of the genome. In this respect, pathogenic conditions may manifest themselves in a changed methylation pattern of individual genes or of the genome.

DNA methylation plays a role, for example, in the regulation of the transcription, in genetic imprinting, and in tumourigenesis. Therefore, the identification of 5-methylcytosine as a component of genetic information is of considerable interest. However, 5-methylcytosine positions cannot be identified by sequencing since 5-methylcytosine has the same base pairing behaviour as cytosine. Moreover, the epigenetic information carried by 5-methylcytosine is completely lost during PCR amplification.

A relatively new and currently the most frequently used method for analysing DNA for 5-methylcytosine is based upon the specific reaction of bisulfite with cytosine which, upon subsequent alkaline hydrolysis, is converted to uracil which corresponds to thymidine in its base pairing behaviour. However, 5-methylcytosine remains unmodified under these conditions. Consequently, the original DNA is converted in such a manner that methylcytosine, which originally could not be distinguished from cytosine by its hybridisation behaviour, can now be detected as the only remaining cytosine using "normal" molecular biological techniques, for example, by amplification and hybridisation or sequencing. All of these techniques are based on base pairing which can now be fully exploited. In terms of sensitivity, the prior art is defined by a method which encloses the DNA to be analysed in an agarose matrix, thus preventing the diffusion and renaturation of the DNA (bisulfite only

reacts with single-stranded DNA), and which replaces all precipitation and purification steps with fast dialysis (Olek A, Oswald J, Walter J. A modified and improved method for bisulphite based cytosine methylation analysis. *Nucleic Acids Res.* 1996 Dec 15;24(24):5064-6). Using this method, it is possible to analyse individual cells, which illustrates the potential of the method. However, currently only individual regions of a length of up to approximately 3000 base pairs are analysed, a global analysis of cells for thousands of possible methylation events is not possible. However, this method cannot reliably analyse very small fragments from small sample quantities either. These are lost through the matrix in spite of the diffusion protection.

An overview of the further known methods of detecting 5-methylcytosine may be gathered from the following review article: Rein, T., DePamphilis, M. L., Zorbas, H., *Nucleic Acids Res.* 1998, 26, 2255.

To date, barring few exceptions (e.g., Zeschnigk M, Lich C, Buiting K, Doerfler W, Horsthemke B. A single-tube PCR test for the diagnosis of Angelman and Prader-Willi syndrome based on allelic methylation differences at the SNRPN locus. *Eur J Hum Genet.* 1997 Mar-Apr;5(2):94-8) the bisulfite technique is only used in research. Always, however, short, specific fragments of a known gene are amplified subsequent to a bisulfite treatment and either completely sequenced (Olek A, Walter J. The pre-implantation ontogeny of the H19 methylation imprint. *Nat Genet.* 1997 Nov;17(3):275-6) or individual cytosine positions are detected by a primer extension reaction (Gonzalzo ML, Jones PA. Rapid quantitation of methylation differences at specific sites using methylation-sensitive single nucleotide primer extension (Ms-SNuPE). *Nucleic Acids Res.* 1997 Jun 15;25(12):2529-31, WO 95/00669) or by enzymatic digestion (Xiong Z, Laird PW. COBRA: a sensitive and quantitative DNA methylation assay. *Nucleic Acids Res.* 1997 Jun 15;25(12):2532-4). In addition, detection by hybridisation has also been described (Olek et al., WO 99/28498).

Further publications dealing with the use of the bisulfite technique for methylation detection in individual genes are: Grigg G, Clark S. Sequencing 5-methylcytosine residues in genomic DNA. *Bioessays.* 1994 Jun;16(6):431-6, 431; Zeschnigk M, Schmitz B, Dittrich B, Buiting K, Horsthemke B, Doerfler W. Imprinted segments in the human genome: different DNA methylation patterns in the Prader-Willi/Angelman syndrome region as determined by the genomic sequencing method. *Hum Mol Genet.* 1997 Mar;6(3):387-95; Feil R, Charlton J,

Bird AP, Walter J, Reik W. Methylation analysis on individual chromosomes: improved protocol for bisulphite genomic sequencing. *Nucleic Acids Res.* 1994 Feb 25;22(4):695-6; Martin V, Ribieras S, Song-Wang X, Rio MC, Dante R. Genomic sequencing indicates a correlation between DNA hypomethylation in the 5' region of the pS2 gene and its expression in human breast cancer cell lines. *Gene.* 1995 May 19;157(1-2):261-4; WO 97/46705, WO 95/15373, and WO 97/45560.

10 An overview of the Prior Art in oligomer array manufacturing can be gathered from a special edition of *Nature Genetics* (*Nature Genetics Supplement*, Volume 21, January 1999), published in January 1999, and from the literature cited therein.

15 Fluorescently labelled probes are often used for the scanning of immobilised DNA arrays. The simple attachment of Cy3 and Cy5 dyes to the 5'-OH of the specific probe are particularly suitable for fluorescence labels. The detection of the fluorescence of the hybridised probes may be carried out, for example via a confocal microscope. Cy3 and Cy5 dyes, besides many others, are commercially available.

20 Matrix Assisted Laser Desorption Ionization Mass Spectrometry (MALDI-TOF) is a very efficient development for the analysis of biomolecules (Karas M, Hillenkamp F. *Laser desorption ionization of proteins with molecular masses exceeding 10,000 daltons.* *Anal Chem.* 1988 Oct 15;60(20):2299-301). An analyte is embedded in a light-absorbing matrix. The matrix is evaporated by a short laser pulse thus transporting the analyte molecule into the vapour phase in an unfragmented manner. The analyte is ionised by collisions with matrix molecules. An applied voltage accelerates the ions into a field-free flight tube. Due to their  
25 different masses, the ions are accelerated at different rates. Smaller ions reach the detector sooner than bigger ones.

30 MALDI-TOF spectrometry is excellently suited to the analysis of peptides and proteins. The analysis of nucleic acids is somewhat more difficult (Gut I G, Beck S. *DNA and Matrix Assisted Laser Desorption Ionization Mass Spectrometry. Current Innovations and Future Trends.* 1995, 1; 147-57). The sensitivity to nucleic acids is approximately 100 times worse than to peptides and decreases disproportionally with increasing fragment size. For nucleic acids having a multiply negatively charged backbone, the ionization process via the matrix is considerably less efficient. In MALDI-TOF spectrometry, the selection of the matrix plays an

eminently important role. For the desorption of peptides, several very efficient matrixes have been found which produce a very fine crystallization. There are now several responsive matrixes for DNA, however, the difference in sensitivity has not been reduced. The difference in sensitivity can be reduced by chemically modifying the DNA in such a manner that it becomes more similar to a peptide. Phosphorothioate nucleic acids in which the usual phosphates of the backbone are substituted with thiophosphates can be converted into a charge-neutral DNA using simple alkylation chemistry (Gut IG, Beck S. A procedure for selective DNA alkylation and detection by mass spectrometry. Nucleic Acids Res. 1995 Apr 25;23(8):1367-73). The coupling of a charge tag to this modified DNA results in an increase in sensitivity to the same level as that found for peptides. A further advantage of charge tagging is the increased stability of the analysis against impurities which make the detection of unmodified substrates considerably more difficult.

Genomic DNA is obtained from DNA of cell, tissue or other test samples using standard methods. This standard methodology is found in references such as Fritsch and Maniatis eds., Molecular Cloning: A Laboratory Manual, 1989.

Breast cancer is currently the second most common type of cancer amongst women. In 2001 over 190,000 new cases of invasive breast cancer and over 47, 000 additional cases of *in situ* breast cancer were diagnosed. Incidence and death rates increase with age, for the period 1994 - 1998 the incidence of breast cancer amongst women between the ages of 20 and 24 was only 1.5 per 100,000 population. However the risk increases to 489.7 within the age group 75 - 79. Mortality rates have decreased by approximately 5% over the last decade and factors affecting 5 year survival rates include age, stage of cancer, socioeconomic factors and race.

Breast cancer is defined as the uncontrolled proliferation of cells within breasts tissues. Breasts are comprised of 15 to 20 lobes joined together by ducts. Cancer arises most commonly in the duct, but is also found in the lobes with the rarest type of cancer termed inflammatory breast cancer.

It will be appreciated by those skilled in the art that there exists a continuing need to improve methods of early detection, classification and treatment of breast cancers. In contrast to the detection of some other common cancers such as cervical and dermal there are inherent difficulties in classifying and detecting breast cancers.

The first step of any treatment is the assessment of the patient's condition comparative to defined classifications of the disease. However the value of such a system is inherently dependant upon the quality of the classification. Breast cancers are staged according to their size, location and occurrence of metastasis. Methods of treatment include the use of surgery, radiation therapy, chemotherapy and endocrine therapy, which are also used as adjuvant therapies to surgery.

Endocrine therapies have been developed in order to block the effects of estrogen on cancer cells or to reduce serum estrogen levels. Tamoxifen (TAM) is the most widely used antioestrogenic drug for breast cancer patients. It acts blocking estrogen stimulation of breast cancer cells, inhibiting both translocation and nuclear binding of estrogen receptor. TAM is used in adjuvant setting for primary breast cancer patients and for the treatment of metastatic disease and its effectiveness has been proved in several clinical trials. Treatment for five years reduces annual disease recurrence by 47% and annual deaths by 26% and this reduction is similar in different age groups. Also it reduces the incidence of developing contralateral breast tumours. TAM is among the least toxic antineoplastic agents but as it has estrogenic properties in some tissues, it increases by 3 folds the risk of endometrial cancer. Other endocrine therapies include aromatase inhibitors, which block the enzyme aromatase in adipose tissue (the main source of estrogen in postmenopausal women) and lead to reduced or abolished production of estrogens in adipose tissue. Also, new agents which block or modulate the estrogen receptor have been developed, they are generally summarised as SERMs = selective estrogen receptor modulators. Yet another way to reduce the amount of estrogen available to the tumour is to apply agents which interrupt the feed-back loop in sex hormone regulation (LH-RH analogues) at a higher level.

In general, the side-effects of endocrine treatment are harmless compared to chemotherapy. However, as endocrine treatments eliminate or reduce estrogen as a growth factor for cancer, they work only for tumours which rely on estrogen as a growth factor. The growth of cancers which do not have a functional ER pathway cannot be modulated by endocrine therapies.

The current way to determine if a tumour will respond to endocrine therapies is the analysis of expression of hormone receptors. Hormone receptor status should be tested prior to any endocrine treatment as only a group of patients will benefit from therapy. For this purpose ER

(estrogen receptor) and PR (progesterone receptor) status are tested routinely in all patients and they are considered predictive markers of response (a predictive marker or factor is any measurement associated with response or lack of response to a particular therapy). ER status is predictive of response in adjuvant endocrine therapy setting and also in advanced metastatic disease.

Currently, ER positive and or PR positive patients receive TAM and the remaining 10% of patients receive chemotherapy. The problem is that the endocrine treatment is only effective in a subgroup of hormone receptor positive patients and also, that a small subgroup of ER negative patients appear initially to respond to TAM. Then, the non responder subgroup will not only not benefit from endocrine treatment but have the adverse effects of it and will not have the opportunity to receive chemotherapy instead. On the other hand, the ER negative subgroup that could have benefit from endocrine treatment will receive instead chemotherapy. Several different assays are available to measure PR and ER, including biochemical and IHC (immunohistochemical) analysis, but there is a lack of standardisation of staining methods and interlaboratory variability (Clin Cancer Res 2000, 6:616-621).

Currently several predictive markers are under evaluation. As up to now most patients have received Tamoxifen as endocrine treatment most of the markers have been shown to be associated with response or resistance to tamoxifen. However, it is generally assumed that there is a large overlap between responders to one or the other endocrine treatment. In fact, ER and PR expression are used to select patients for any endocrine treatment. Among the markers which have been associated with TAM response is bcl-2. High bcl-2 levels showed promising correlation to TAM therapy response in patients with metastatic disease and prolonged survival and added valuable information to ER negative patient subgroup (J Clin Oncology 1997, 15 5:1916-1922; Endocrine, 2000, 13(1):1-10). There is conflicting evidence regarding the independent predictive value of c-erbB2 (Her2/neu) over expression in patients with advance breast cancer that require further evaluation and verification (British J of Cancer, 1999, 79 (7/8):1220-1226; J Natl Cancer Inst, 1998, 90 (21): 1601-1608).

Other predictive markers include SRC-1 (steroid receptor coactivator-1), CGA gene over expression, cell kinetics and S phase fraction assays (Breast Cancer Res and Treat, 1998, 48:87-92; Oncogene 2001, 20:6955-6959). Recently, uPA (Urokinase-type plasminogen activator) and PAI-1 (Plasminogen activator inhibitor type 1) together showed to be useful to

define a subgroup of patients who have worse prognosis and who would benefit from adjuvant systemic therapy (J Clinical Oncology, 2002, 20 n° 4). All of these markers need further evaluations in prospective trials as none of them is yet a validated marker of response.

5 A number of cancer-associated genes have been shown to be inactivated by hypermethylation of CpG islands during breast tumourigenesis. Decreased expression of the calcium binding protein S100A2 (Accession number NM\_005978) has been associated with the development of breast cancers. Hypermethylation of the promoter region of this gene has been observed in neoplastic cells thus providing evidence that S100A2 repression in tumour cells is mediated  
10 by site-specific methylation.

The SYK gene (Accession number NM\_003177) encodes a protein tyrosine kinase, Syk (spleen tyrosine kinase), that is highly expressed in hematopoietic cells. Syk is expressed in normal breast ductal epithelial cells but not in a subset of invasive breast carcinoma. Also, the  
15 loss of Syk expression seems to be associated with malignant phenotypes such as increased motility and invasion. The loss of expression occurs at the transcriptional level, and, as indicated by Yuan Y, Mendez R, Sahin A and Dai JL (Hypermethylation leads to silencing of the SYK gene in human breast cancer. Cancer Res. 2001;61(14):5558-61.), as a result of DNA hypermethylation.

20 The TGF- $\beta$  type 2 receptor (encoded by the TGFBR2 gene, NM\_003242) plays a role in trans-membrane signalling pathways via a complex of serine/threonine kinases. Mutations in the gene have been detected in some primary tumours and in several types of tumour-derived cell lines, including breast (Lucke CD, Philpott A, Metcalfe JC, Thompson AM, Hughes-  
25 Davies L, Kemp PR, Hesketh R. Inhibiting mutations in the transforming growth factor beta type 2 receptor in recurrent human breast cancer. Cancer Res. 2001 Jan 15;61(2):482-5).

The genes COX7A2L and GRIN2D were both identified as novel estrogen responsive elements by Watanabe et. al. (Isolation of estrogen-responsive genes with a CpG island  
30 library. Molec. Cell. Biol. 18: 442-449, 1998.) using the CpG-GBS (genomic binding site) method. The gene COX7A2L (Accession number NM\_004718 encodes a polypeptide 2-like cytochrome C oxidase subunit VIIA. Northern blot analysis detected an upregulation of COX7A2L after estrogen treatment of a breast cancer cell line. The gene GRIN2D (Accession number NM\_000836) encodes the N-methyl-D-aspartate, ionotropic, subunit 2D glutamate

receptor, a subunit of the NMDA receptor channels associated with neuronal signalling, furthermore expression of the cDNA has been observed in an osteosarcoma cell line. The gene VTN (also known as Vitronectin Accession number NM\_000638) encodes a 75-kD glycoprotein (also called serum spreading factor or complement S-protein) that promotes attachment and spreading of animal cells in vitro, inhibits cytolysis by the complement C5b-9 complex, and modulates antithrombin III-thrombin action in blood coagulation. Furthermore expression of this gene has been linked to progression and invasiveness of cancer cells.

The gene SFN (also known as Stratifin) encodes a polypeptide of the 14-3-3 family, 14-3-3 sigma. The 14-3-3 family of proteins mediates signal transduction by binding to phosphoserine-containing proteins. Expression of the SFN gene is lost in breast carcinomas, this is likely due to hypermethylation during the early stages of neoplastic transformation (see Umbricht CB, Evron E, Gabrielson E, Ferguson A, Marks J, Sukumar S. Hypermethylation of 14-3-3 sigma (stratifin) is an early event in breast cancer. *Oncogene*. 2001 Jun 7;20(26):3348-53).

The gene PSA (Accession number NM\_021154), also known as PSA-T, is not to be confused with the gene also popularly referred to as PSA (Accession number NM\_001648) which encodes prostate specific antigen and whose technically correct name is kallikrein 3. The gene PSA-T encodes the protein phosphoserine aminotransferase which is the second step-catalysing enzyme in the serine biosynthesis pathway. Changes in gene expression levels have been monitored by mRNA expression analysis and upregulation of the gene has been identified in colonic carcinoma in a study of 6 samples (Ojala P, Sundstrom J, Gronroos JM, Virtanen E, Talvinen K, Nevalainen TJ. mRNA differential display of gene expression in colonic carcinoma. *Electrophoresis*. 2002; 23(11):1667-76).

The gene stathimin (NM\_005563) codes for an oncoprotein 18, also known as stathimin, a conserved cytosolic phosphoprotein that regulates microtubule dynamics. The protein is highly expressed in a variety of human malignancies. In human breast cancers the stathimin gene has shown to be up-regulated in a subset of the tumours. The gene PRKCD encodes a member of the family of protein kinase c enzymes, and is involved in B cell signalling and in the regulation of growth, apoptosis, and differentiation of a variety of cell types.

Some of these molecules interact in a cascade-like manner. PRKCD activity that targets STMN1 is modulated by SFN binding and SYK phosphorylation. Together this influences tubulin polymerisation that is required for cell division.

### Description

5

10

15

The present invention provides methods and nucleic acids for predicting the response of a patient with a cell proliferative disorder of the breast tissues to endocrine treatment. Using the methods and nucleic acids described herein, statistically significant models of patient responsiveness to said treatment regimen can be developed and utilised to assist patients and clinicians in determining treatment options. The described method is to be used to assess the suitability of endocrine treatment as a therapy for patients suffering from a cell proliferative disorder of the breast tissues. Thus, the present invention will be seen to reduce the problems associated with present treatment response prediction methods.

20

Using the methods and nucleic acids as described herein, patient responsiveness can be evaluated before or during endocrine treatment for a cell proliferative disorder of the breast tissues, in order to provide critical information to the patient and clinician as to the risks, burdens, and benefits associated endocrine treatment. It will be appreciated, therefore, that the methods and nucleic acids exemplified herein can serve to improve a patient's quality of life and odds of treatment success by allowing both patient and clinician a more accurate assessment of the patient's treatment options.

25

30

The aim of the invention is achieved by means of the analysis of the methylation patterns of one or a combination of genes taken from the group PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2, COX7A2L (see Table 1) and/or their regulatory regions. The invention is characterised in that the nucleic acid of one or a combination of genes taken from the group PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L are contacted with a reagent or series of reagents capable of distinguishing between methylated and non methylated CpG dinucleotides within the genomic sequence of interest.

The present invention makes available a method for ascertaining genetic and/or epigenetic parameters of genomic DNA. The method is for use in the improved treatment and monitoring of breast cell proliferative disorders, by enabling the accurate prediction of a patient's response to endocrine treatment. In a particularly preferred embodiment, the method according to the invention enables the differentiation between patients who respond to endocrine therapy and those who do not.

The method according to the invention may be used for the analysis of a wide variety of cell proliferative disorders of the breast tissues including, but not limited to ductal carcinoma *in situ*, lobular carcinoma, colloid carcinoma, tubular carcinoma, medullary carcinoma, metaplastic carcinoma, intraductal carcinoma *in situ*, lobular carcinoma *in situ* and papillary carcinoma *in situ*.

The method according to the invention is particularly suited to the prediction of response to endocrine treatment in two treatment settings. In one embodiment, the method is applied to patients who receive endocrine treatment as secondary treatment to a primary treatment such as surgery (hereinafter referred to as the adjuvant setting) as illustrated in Figure 1. Such a treatment is often prescribed to patients suffering from Stage 1 to 3 breast carcinomas. In this embodiment responders are defined as those who do not have a detectable relapse of the breast cancer in a specified period of time, non responders are those who relapse within said time period.

In a further preferred embodiment said method is applied to patients suffering from a relapse of breast cancer following treatment by a primary means (preferably surgery), followed by a disease free period, and wherein the endocrine treatment has been prescribed in response to a detection of a relapse of the carcinoma. Such a treatment is often prescribed to patients suffering from later stage carcinomas, particularly wherein metastasis has occurred. Therefore this clinical setting shall also hereinafter be referred to as the 'metastatic setting'. In this embodiment responders are those who enter partial or complete remission i.e. subjects whose cancer recedes to undetectable levels as opposed to those whose diseases further metastasise or remain above detectable levels. This methodology present further improvements over the state of the art in that the method may be applied to any subject, independent of the estrogen and/or progesterone receptor status. Therefore in a preferred embodiment, the subject is not required to have been tested for estrogen or progesterone receptor status.

Furthermore, the method enables the analysis of cytosine methylations and single nucleotide polymorphisms within said genes.

5 The object of the invention is achieved by means of the analysis of the methylation patterns of the genes PSA; STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L and/or their regulatory regions, in a particularly preferred embodiment, the sequences comprising SEQ ID NOs: 27, 90, 41, 40, 121, 78, 115, 86, 43 and 105 and sequences complementary thereto. In a preferred embodiment said method is achieved by  
10 contacting said nucleic acid sequences in a biological sample obtained from a subject with at least one reagent or a series of reagents, wherein said reagent or series of reagents, distinguishes between methylated and non methylated CpG dinucleotides within the target nucleic acid.

15 In a preferred embodiment, the method comprises the following steps:  
In the first step of the method the genomic DNA sample must be isolated from sources such as cells or cellular components which contain DNA, sources of DNA comprising, for example, cell lines, histological slides, biopsies, tissue embedded in paraffin, breast tissues, blood, plasma, lymphatic fluid, lymphatic tissue, duct cells, ductal lavage fluid, nipple  
20 aspiration fluid, bone marrow and combinations thereof. Extraction may be by means that are standard to one skilled in the art, these include the use of detergent lysates, sonification and vortexing with glass beads. Once the nucleic acids have been extracted the genomic double stranded DNA is used in the analysis.

25 In a preferred embodiment the DNA may be cleaved prior to the next step of the method, this may be by any means standard in the state of the art, in particular, but not limited to, with restriction endonucleases.

In the second step of the method, the genomic DNA sample is treated in such a manner that  
30 cytosine bases which are unmethylated at the 5'-position are converted to uracil, thymine, or another base which is dissimilar to cytosine in terms of hybridisation behaviour. This will be understood as 'pretreatment' hereinafter.

The above described treatment of genomic DNA is preferably carried out with bisulfite (sulfite, disulfite) and subsequent alkaline hydrolysis which results in a conversion of non-methylated cytosine nucleobases to uracil or to another base which is dissimilar to cytosine in terms of base pairing behaviour. If bisulfite solution is used for the reaction, then an addition  
5 takes place at the non-methylated cytosine bases. Moreover, a denaturing reagent or solvent as well as a radical interceptor must be present. A subsequent alkaline hydrolysis then gives rise to the conversion of non-methylated cytosine nucleobases to uracil. The converted DNA is then used for the detection of methylated cytosines.

10 Fragments of the pretreated DNA are amplified, using sets of primer oligonucleotides, and a preferably heat-stable, polymerase. Because of statistical and practical considerations, preferably more than six different fragments having a length of 100 - 2000 base pairs are amplified. The amplification of several DNA segments can be carried out simultaneously in one and the same reaction vessel. Usually, the amplification is carried out by means of a  
15 polymerase chain reaction (PCR).

The design of such primers is obvious to one skilled in the art. These should include at least two oligonucleotides whose sequences are each reverse complementary or identical to an at least 18 base-pair long segment of the following base sequences specified in the appendix:

20 SEQ ID NO.188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587.

Said primer oligonucleotides are preferably characterised in that they do not contain any CpG dinucleotides. In a particularly preferred embodiment of the method, the sequence of said  
25 primer oligonucleotides are designed so as to selectively anneal to and amplify, only the breast cell specific DNA of interest, thereby minimising the amplification of background or non relevant DNA. In the context of the present invention, background DNA is taken to mean genomic DNA which does not have a relevant tissue specific methylation pattern, in this case, the relevant tissue being breast tissues.

30 According to the present invention, it is preferred that at least one primer oligonucleotide is bound to a solid phase during amplification. The different oligonucleotide and/or PNA-oligomer sequences can be arranged on a plane solid phase in the form of a rectangular or hexagonal lattice, the solid phase surface preferably being composed of silicon, glass,

polystyrene, aluminium, steel, iron, copper, nickel, silver, or gold, it being possible for other materials such as nitrocellulose or plastics to be used as well.

5 The fragments obtained by means of the amplification may carry a directly or indirectly detectable label. Preferred are labels in the form of fluorescence labels, radionuclides, or detachable molecule fragments having a typical mass which can be detected in a mass spectrometer, it being preferred that the fragments that are produced have a single positive or negative net charge for better detectability in the mass spectrometer. The detection may be carried out and visualised by means of matrix assisted laser desorption/ionisation mass  
10 spectrometry (MALDI) or using electron spray mass spectrometry (ESI).

In the next step the nucleic acid amplificates are analysed in order to determine the methylation status of the genomic DNA prior to treatment.

15 The post treatment analysis of the nucleic acids may be carried out using alternative methods. Several methods for the methylation status specific analysis of the treated nucleic acids are described below, other alternative methods will be obvious to one skilled in the art.

Using several methods known in the art the analysis may be carried out during the  
20 amplification step of the method. In one such embodiment, the methylation status of preselected CpG positions within the genes PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2, COX7A2L PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L and/or their regulatory regions may be detected by use of methylation specific primer oligonucleotides. This technique has been described in U.S.  
25 Patent 6,265,171 to Herman. The use of methylation status specific primers for the amplification of bisulphite treated DNA allows the differentiation between methylated and unmethylated nucleic acids. MSP primers pairs contain at least one primer which hybridises to a bisulphite treated CpG dinucleotide. Therefore the sequence of said primers comprises at least one CG, TG or CA dinucleotide. MSP primers specific for non methylated DNA contain  
30 a 'T' at the 3' position of the C position in the CpG. According to the present invention, it is therefore preferred that the base sequence of said primers is required to comprise a sequence having a length of at least 9 nucleotides which hybridises to a pretreated nucleic acid sequence according to SEQ ID NOs.: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463,

344, 345, 586 and 587 and sequences complementary thereto wherein the base sequence of said oligomers comprises at least one CG, TG or CA dinucleotide.

5 In one embodiment of the method the methylation status of the CpG positions may be determined by means of hybridisation analysis. In this embodiment of the method the amplicates obtained in the second step of the method are hybridised to an array or a set of oligonucleotides and/or PNA probes. In this context, the hybridisation takes place in the manner described as follows. The set of probes used during the hybridisation is preferably composed of at least 4 oligonucleotides or PNA-oligomers. In the process, the amplicates  
10 serve as probes which hybridise to oligonucleotides previously bonded to a solid phase. The non-hybridised fragments are subsequently removed. Said oligonucleotides contain at least one base sequence having a length of 10 nucleotides which is reverse complementary or identical to a segment of the base sequences specified in the appendix, the segment containing at least one CpG or TpG dinucleotide. In a further preferred embodiment the cytosine of the  
15 CpG dinucleotide, or in the case of TpG, the thiamine, is the 5<sup>th</sup> to 9<sup>th</sup> nucleotide from the 5'-end of the 10-mer. One oligonucleotide exists for each CpG or TpG dinucleotide.

The non-hybridised amplicates are then removed. In the final step of the method, the hybridised amplicates are detected. In this context, it is preferred that labels attached to the  
20 amplicates are identifiable at each position of the solid phase at which an oligonucleotide sequence is located.

In a further embodiment of the method the methylation status of the CpG positions may be determined by means of oligonucleotide probes that are hybridised to the treated DNA  
25 concurrently with the PCR amplification primers (wherein said primers may either be methylation specific or standard).

A particularly preferred embodiment of this method is the use of fluorescence-based Real Time Quantitative PCR (Heid et al., Genome Res. 6:986-994, 1996) employing a dual-  
30 labelled fluorescent oligonucleotide probe (TaqMan™ PCR, using an ABI Prism 7700 Sequence Detection System, Perkin Elmer Applied Biosystems, Foster City, California). The TaqMan™ PCR reaction employs the use of a nonextendible interrogating oligonucleotide, called a TaqMan™ probe, which is designed to hybridise to a GpC-rich sequence located between the forward and reverse amplification primers. The TaqMan™ probe further

comprises a fluorescent "reporter moiety" and a "quencher moiety" covalently bound to linker moieties (e.g., phosphoramidites) attached to the nucleotides of the TaqMan™ oligonucleotide. For analysis of methylation within nucleic acids subsequent to bisulphite treatment it is required that the probe be methylation specific, as described in U.S. 6,331,393, (hereby incorporated by reference) also known as the Methyl Light assay. Variations on the TaqMan™ detection methodology that are also suitable for use with the described invention include the use of dual probe technology (Lightcycler™) or fluorescent amplification primers (Sunrise™ technology). Both these techniques may be adapted in a manner suitable for use with bisulphite treated DNA, and moreover for methylation analysis within CpG dinucleotides.

A further suitable method for the use of probe oligonucleotides for the assessment of methylation by analysis of bisulphite treated nucleic acids is the use of blocker oligonucleotides. The use of such oligonucleotides has been described in BioTechniques 23(4), 1997, 714-720 D. Yu, M.Mukai, Q. Liu, C. Steinman. Blocking probe oligonucleotides are hybridised to the bisulphite treated nucleic acid concurrently with the PCR primers. PCR amplification of the nucleic acid is terminated at the 5' position of the blocking probe, thereby amplification of a nucleic acid is suppressed wherein the complementary sequence to the blocking probe is present. The probes may be designed to hybridise to the bisulphite treated nucleic acid in a methylation status specific manner. For example, for detection of methylated nucleic acids within a population of unmethylated nucleic acids suppression of the amplification of nucleic acids which are unmethylated at the position in question would be carried out by the use of blocking probes comprising a 'CG' at the position in question, as opposed to a 'CA'.

In a further preferred embodiment of the method the determination of the methylation status of the CpG positions is carried out by the use of template directed oligonucleotide extension, such as MS SNUPE as described by Gonzalgo and Jones (Nucleic Acids Res. 25:2529-2531).

In a further embodiment of the method the determination of the methylation status of the CpG positions is enabled by sequencing and subsequent sequence analysis of the amplicate generated in the second step of the method (Sanger F., et al., 1977 PNAS USA 74: 5463-5467).

A further embodiment of the invention is a method for the analysis of the methylation status of genomic DNA without the need for pretreatment. In the first and second steps of the method the genomic DNA sample must be obtained and isolated from tissue or cellular sources. Such sources may include cell lines, histological slides, body fluids, or tissue  
5 embedded in paraffin. Extraction may be by means that are standard to one skilled in the art, these include the use of detergent lysates, sonification and vortexing with glass beads. Once the nucleic acids have been extracted the genomic double stranded DNA is used in the analysis.

10 In a preferred embodiment the DNA may be cleaved prior to the treatment, this may be by any means standard in the state of the art, in particular with restriction endonucleases. In the third step, the DNA is then digested with one or more methylation sensitive restriction enzymes. The digestion is carried out such that hydrolysis of the DNA at the restriction site is informative of the methylation status of a specific CpG dinucleotide.

15 In a preferred embodiment the restriction fragments are amplified. In a further preferred embodiment this is carried out using the polymerase chain reaction.

In the final step the amplicates are detected. The detection may be by any means standard in  
20 the art, for example, but not limited to, gel electrophoresis analysis, hybridisation analysis, incorporation of detectable tags within the PCR products, DNA array analysis, MALDI or ESI analysis.

25 The aforementioned method is preferably used for ascertaining genetic and/or epigenetic parameters of genomic DNA.

In order to enable this method, the invention further provides the modified DNA of one or a combination of genes taken from the group PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2, COX7A2L. PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN,  
30 GRIN2D, TGFBR2 and COX7A2L as well as oligonucleotides and/or PNA-oligomers for detecting cytosine methylations within said genes. The present invention is based on the discovery that genetic and epigenetic parameters and, in particular, the cytosine methylation patterns of said genomic DNAs are particularly suitable for improved treatment and monitoring of breast cell proliferative disorders.

The nucleic acids according to the present invention can be used for the analysis of genetic and/or epigenetic parameters of genomic DNA.

5 This objective according to the present invention is achieved using a nucleic acid containing a sequence of at least 18 bases in length of the pretreated genomic DNA according to one of SEQ ID NOs: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586, 587, 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365,  
10 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587 and sequences complementary thereto.

The modified nucleic acids could heretofore not be connected with the ascertainment of disease relevant genetic and epigenetic parameters.

15 The object of the present invention is further achieved by an oligonucleotide or oligomer for the analysis of pretreated DNA, for detecting the genomic cytosine methylation state, said oligonucleotide containing at least one base sequence having a length of at least 10 nucleotides which hybridises to a pretreated genomic DNA according to SEQ ID NOs: 188,  
20 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587. The oligomer probes according to the present invention constitute important and effective tools which, for the first time, make it possible to ascertain specific genetic and epigenetic parameters during the analysis of biological samples for features associated with a patient's response to endocrine  
25 treatment. Said oligonucleotides allow the improved treatment and monitoring of breast cell proliferative disorders. The base sequence of the oligomers preferably contains at least one CpG or TpG dinucleotide. The probes may also exist in the form of a PNA (peptide nucleic acid) which has particularly preferred pairing properties. Particularly preferred are oligonucleotides according to the present invention in which the cytosine of the CpG  
30 dinucleotide is within the middle third of said oligonucleotide e.g. the 5<sup>th</sup> - 9<sup>th</sup> nucleotide from the 5'-end of a 13-mer oligonucleotide; or in the case of PNA-oligomers, it is preferred for the cytosine of the CpG dinucleotide to be the 4<sup>th</sup> - 6<sup>th</sup> nucleotide from the 5'-end of the 9-mer.

The oligomers according to the present invention are normally used in so called "sets" which contain at least one oligomer for each of the CpG dinucleotides within SEQ ID NOs: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587.

5 In a particularly preferred embodiment of the method the oligomers according to SEQ ID NOs: 1816-1833, 1114-1129, 1808-1815, 1762-1769, 1552-1559, 1490-1499, 1138-1147 and 1686-1693 are used for predicting a subject's response to endocrine treatment in an metastatic setting.

10 In the case of the sets of oligonucleotides according to the present invention, it is preferred that at least one oligonucleotide is bound to a solid phase. It is further preferred that all the oligonucleotides of one set are bound to a solid phase.

15 The present invention further relates to a set of at least 10 n (oligonucleotides and/or PNA-oligomers) used for detecting the cytosine methylation state of genomic DNA, by analysis of said sequence or treated versions of said sequence (of the genes PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L, as detailed in the sequence listing and Table 1) and sequences complementary thereto). These probes enable improved treatment  
20 and monitoring of breast cell proliferative disorders.

The set of oligomers may also be used for detecting single nucleotide polymorphisms (SNPs) by analysis of said sequence or treated versions of said sequence (of the genes PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L, as detailed in the  
25 sequence listing and Table 1).

It will be obvious to one skilled in the art that the method according to the invention will be improved and supplemented by the incorporation of markers and clinical indicators known in the state of the art and currently used as predictive of the outcome Endocrine treatment. More  
30 preferably said markers include node status, age, menopausal status, grade, estrogen and progesterone receptors.

The genes that form the basis of the present invention may also be used to form a "gene panel", i.e. a collection comprising the particular genetic sequences of the present invention

and/or their respective informative methylation sites. The formation of gene panels allows for a quick and specific analysis of specific aspects of breast cancer treatment. The gene panel(s) as described and employed in this invention can be used with surprisingly high efficiency for the treatment of breast cell proliferative disorders by prediction of the outcome of treatment with a therapy comprising one or more drugs which target the estrogen receptor pathway or are involved in estrogen metabolism, production, or secretion.

The efficiency of the method according to the invention is improved when applied to patients who have not been treated with chemotherapy. Accordingly, it is a particularly preferred embodiment of the method wherein the method is used for the assessment of subjects who have not undergone chemotherapy.

In addition, the use of multiple CpG sites from a diverse array of genes allows for a relatively high degree of sensitivity and specificity in comparison to single gene prognostic tools.

According to the present invention, it is preferred that an arrangement of different oligonucleotides and/or PNA-oligomers (a so-called "array") made available by the present invention is present in a manner that it is likewise bound to a solid phase. This array of different oligonucleotide- and/or PNA-oligomer sequences can be characterised in that it is arranged on the solid phase in the form of a rectangular or hexagonal lattice. The solid phase surface is preferably composed of silicon, glass, polystyrene, aluminium, steel, iron, copper, nickel, silver, or gold. However, nitrocellulose as well as plastics such as nylon which can exist in the form of pellets or also as resin matrices are suitable alternatives.

Therefore, a further subject matter of the present invention is a method for manufacturing an array fixed to a carrier material for the improved treatment and monitoring of breast cell proliferative disorders. In said method at least one oligomer according to the present invention is coupled to a solid phase. Methods for manufacturing such arrays are known, for example, from US Patent 5,744,305 by means of solid-phase chemistry and photolabile protecting groups.

A further subject matter of the present invention relates to a DNA chip for the improved treatment and monitoring of breast cell proliferative disorders. The DNA chip contains at least

one nucleic acid according to the present invention. DNA chips are known, for example, in US Patent 5,837,832.

Moreover, a subject matter of the present invention is a kit which may be composed, for example, of a bisulfite-containing reagent, a set of primer oligonucleotides containing at least two oligonucleotides whose sequences in each case correspond to or are complementary to a 18 base long segment of the base sequences specified in SEQ ID NOs: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587 and/or PNA-oligomers as well as instructions for carrying out and evaluating the described method.

In a further preferred embodiment said kit may further comprise standard reagents for performing a CpG position specific methylation analysis wherein said analysis comprises one or more of the following techniques: MS-SNuPE, MSP, Methyl light, Heavy Methyl, and nucleic acid sequencing. However, a kit along the lines of the present invention can also contain only part of the aforementioned components.

The oligomers according to the present invention or arrays thereof as well as a kit according to the present invention are intended to be used for the improved treatment and monitoring of breast cell proliferative disorders. According to the present invention, the method is preferably used for the analysis of important genetic and/or epigenetic parameters within genomic DNA, in particular for use in improved treatment and monitoring of breast cell proliferative disorders.

The methods according to the present invention are used, for improved treatment and monitoring of breast cell proliferative disorder by enabling more informed treatment regimens.

The present invention moreover relates to the diagnosis and/or prognosis of events which are disadvantageous or relevant to patients or individuals in which important genetic and/or epigenetic parameters within genomic DNA, said parameters obtained by means of the present invention may be compared to another set of genetic and/or epigenetic parameters, the differences serving as the basis for the diagnosis and/or prognosis of events which are

disadvantageous or relevant to patients or individuals. Examples of such parameters include, but are not limited to the assessment of estrogen and progesterone markers.

5 In the context of the present invention the term "hybridisation" is to be understood as a bond of an oligonucleotide to a completely complementary sequence along the lines of the Watson-Crick base pairings in the sample DNA, forming a duplex structure.

10 In the context of the present invention, "genetic parameters" are mutations and polymorphisms of genomic DNA and sequences further required for their regulation. To be designated as mutations are, in particular, insertions, deletions, point mutations, inversions and polymorphisms and, particularly preferred, SNPs (single nucleotide polymorphisms).

15 In the context of the present invention the term "methylation state" is taken to mean the degree of methylation present in a nucleic acid of interest, this may be expressed in absolute or relative terms i.e. as a percentage or other numerical value or by comparison to another tissue and therein described as hypermethylated, hypomethylated or as having significantly similar or identical methylation status.

20 In the context of the present invention the term "regulatory region" of a gene is taken to mean nucleotide sequences which affect the expression of a gene. Said regulatory regions may be located within, proximal or distal to said gene. Said regulatory regions include but are not limited to constitutive promoters, tissue-specific promoters, developmental-specific promoters, inducible promoters and the like. Promoter regulatory elements may also include certain enhancer sequence elements that control transcriptional or translational efficiency of the gene.

25 In the context of the present invention the term "chemotherapy" is taken to mean the use of drugs or chemical substances to treat cancer. This definition excludes radiation therapy (treatment with high energy rays or particles), hormone therapy (treatment with hormones or hormone analogues (synthetic substitutes) and surgical treatment.

30 In the context of the present invention, "epigenetic parameters" are, in particular, cytosine methylations and further modifications of DNA bases of genomic DNA and sequences further required for their regulation. Further epigenetic parameters include, for example, the

acetylation of histones which, cannot be directly analysed using the described method but which, in turn, correlates with the DNA methylation.

In the context of the present invention the term "adjuvant treatment" is taken to mean a therapy of a cancer patient immediately following an initial non chemotherapeutical therapy, e.g. surgery. In the context of the present invention, said adjuvant treatment is performed using Tamoxifen. In general, the purpose of an adjuvant therapy is to provide a significantly smaller risk of recurrences compared without the adjuvant therapy.

In the context of the present invention the term "estrogen and/or progesterone receptor positive" is taken to mean cells that expresses on its surface receptors that are susceptible to the binding of estrogens and/or progesterones.

In the following, the present invention will be explained in greater detail on the basis of the sequences, figures and examples without being limited thereto.

Figure 1 shows a preferred application of the method according to the invention. The X axis shows the tumour(s) mass, wherein the line '3' shows the limit of detectability. The Y-axis shows time. Accordingly said figure illustrates a simplified model of endocrine treatment of an Stage 1-3 breast tumour wherein primary treatment was surgery (at point 1), followed by adjuvant therapy with Tamoxifen. In a first scenario a responder to treatment (4) is shown as remaining below the limit of detectability for the duration of the observation. A non responder to the treatment (5) has a period of disease free survival (2) followed by relapse when the carcinoma mass reaches the level of detectability.

Figure 2 shows another preferred application of the method according to the invention. The X axis shows the tumour(s) mass, wherein the line '3' shows the limit of detectability. The Y-axis shows time. Accordingly said figure illustrates a simplified model of Endocrine treatment of an late stage breast tumour wherein primary treatment was surgery (at point 1), followed by relapse which is treated by Tamoxifen (2). In a first scenario a responder to treatment (4) is shown as remaining below the limit of detectability for the duration of the observation. A non responder to the treatment (5) does not recover from the relapse.

Figure 3 shows the methylation analysis of CpG islands according to Example 1. CpG islands per gene were grouped and their correlation with objective response determined by Hotelling's  $T^2$  statistics. Black dots indicate the  $P$ -value of the indicated gene. The 20 most informative genes, ranked from left to right with increasing  $P$ -value, are shown. The top dotted line marks the uncorrected significance value ( $P < 0.05$ ). The lower dotted line marks significance after false discovery rate correction of 25%. All genes with a  $P$ -value smaller or equal to the gene with the largest  $P$ -value that is below the lower line (in this case COX7A2L) are considered significant. The FDR correction chosen guarantees that the identified genes are with 75% chance true discoveries.

Figure 4 shows the raw CpG dinucleotide methylation data of the 10 genes that significantly correlated with the overall response rate as determined in Figure 3 (Example 1). Tumours from objective responders (CR + PR) are shown on the left; tumours from patients with progressive disease (PD) are shown on the right. The shades of grey represent the relative distance of the CpG dinucleotide methylation status from the mean value. CpG dinucleotides are grouped per gene. The indicated genes are ordered from top to bottom with increasing significance. Light grey represents a hypomethylated CpG dinucleotide while darker grey indicates a hypermethylated CpG dinucleotide. Methylation data are centered and normalised to one standard deviation for every individual CpG dinucleotide.

Figure 5 shows the progression-free survival (PFS) curves of combination scores according to Example 1. PFS curves after start of tamoxifen treatment of patients are shown. They are grouped using a predictive score ( $\chi^2=14.0$ ; 3 degrees of freedom) based on the traditional predictive markers age, dominant site of relapse, disease-free interval and ER level (A). A DNA methylation-based score ( $\chi^2=27.5$ ; 3 degrees of freedom) is presented comprising the statistically independent predicting genes phosphoserine amino transferase (PSA-T), stathmin (STMN1), S100 protein A2 (S100A2), transforming growth factor  $\beta$  receptor II (TGFB2), and glutamate receptor 2D (GRIN2D) (B). Survival curves were generated and significance calculated as described in Example 1. The calculated predictive scores were divided into 4 groups (q1 – q4) with 50 patients each and using the 25<sup>th</sup>, 50<sup>th</sup>, and 75<sup>th</sup> percentile of the values. The numbers below the X-axis represent the number of patients at risk in each group at the indicated time points of 0, 12, 24, and 36 months. Progression free survival (in percentage) is plotted on the Y-axis and time to progression (in months) is plotted on the X-axis.

SEQ ID NOs: 1 to 121 represent 5' and/or regulatory regions and/or CpG rich regions of the genes according to Table 1. These sequences are derived from Genbank and will be taken to include all minor variations of the sequence material which are currently unforeseen, for example, but not limited to, minor deletions and SNPs.

SEQ ID NOs: 136 to 619 exhibit the pretreated sequence of DNA derived from the genomic sequence according to Table 1. These sequences will be taken to include all minor variations of the sequence material which are currently unforeseen, for example, but not limited to, minor deletions and SNPs.

SEQ ID NO: 856 to SEQ ID NO: 1843 exhibit the sequence of oligomers which are particularly useful for the analysis of pretreated DNA according to SEQ ID NO: 136 to SEQ ID NO: 619.

### **Examples**

In the following example, candidate genes were analysed by means of high throughput methylation analysis methods. A set of 200 breast cancer samples from advanced breast cancer patients, treated with the anti-estrogen drug tamoxifen were analyzed. The measurable effect of endocrine therapy on the size of the metastatic lesion, and on progression free survival time (PFS) was used as the main clinical endpoints of the study. In total, 499 CpGs in the promoter regions of 117 genes (2 to 6 CpGs per gene) were analyzed.

### **Example 1**

In the first step the genomic DNA was isolated from the cell samples using the Wizzard kit (Promega).

The isolated genomic DNA from the samples were treated using a bisulfite solution (hydrogen sulfite, disulfite). The treatment was such that all non methylated cytosines within the sample were converted to thiamidine, conversely 5-methylated cytosines within the sample remain unmodified.

The treated nucleic acids were then amplified using multiplex PCRs, amplifying 8 fragments per reaction with Cy5 fluorescently labelled primers. PCR primers used are described in Table 2. PCR conditions were as follows.

5    Reaction solution:

10 ng bisulfite treated DNA

3,5 mmol/l MgCl<sub>2</sub>

400 µmol/l dNTPs

2 pmol each primer

10    1 U Hot Star Taq (Qiagen)

Forty cycles were carried out as follows. Denaturation at 95°C for 15 min, followed by annealing at 55°C for 45 sec, primer elongation at 65°C for 2 min. A final elongation at 65°C was carried out for 10 min.

15

All PCR products from each individual sample were then hybridised to glass slides carrying a pair of immobilised oligonucleotides for each CpG position under analysis. Each of these detection oligonucleotides was designed to hybridise to the bisulphite converted sequence around one CpG site which was either originally unmethylated (TG) or methylated (CG). See Table 2 for further details of all hybridisation oligonucleotides used. Hybridisation conditions were selected to allow the detection of the single nucleotide differences between the TG and CG variants.

20

5 µl volume of each multiplex PCR product was diluted in 10 x Ssarc buffer (10 x Ssarc: 230 ml 20 x SSC, 180 ml sodium lauroyl sarcosinate solution 20%, dilute to 1000 ml with dH<sub>2</sub>O).

25

The reaction mixture was then hybridised to the detection oligonucleotides as follows. Denaturation at 95°C, cooling down to 10°C, hybridisation at 42°C overnight followed by washing with 10 x Ssarc and dH<sub>2</sub>O at 42°C.

30

Fluorescent signals from each hybridised oligonucleotide were detected using genepix scanner and software. Ratios for the two signals (from the CG oligonucleotide and the TG oligonucleotide used to analyse each CpG position) were calculated based on comparison of intensity of the fluorescent signals.

### Data analysis

In order to determine the ability of each gene promoter to predict success or failure of Tamoxifen treatment, the individual CpGs measured were combined per gene using Hotelling's  $T^2$  statistics. To identify potential markers, we performed our initial analysis on those 123 patients who showed the extreme types of response; either an objective response (CR+PR, 45 patients) or a progressive disease right from the start of treatment (PD, 78 patients). Ten genes were significantly associated with a response to tamoxifen after correcting for multiple comparison with a moderate conservative false discovery rate of 25% (see Figure 3). The genes were PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L. Furthermore, from the DNA methylation data matrix (Figure 4), we concluded that for the majority of the genes CpG island hypermethylation was correlated with favourable response to tamoxifen treatment, while for stathmin 1/oncoprotein 18 (STMN1) and stratifin/14-3-3 protein  $\sigma$  (SFN) hypomethylation was associated with remission.

Subsequently, all 200 patients including those with an intermediate type of response (59 patients with stable disease (SD, no change of disease for more than 6 months) and 18 patients with stable disease for 6 months or less) were analysed in logistic regression analysis. For each of the 10 selected genes, we combined per gene the estimates from the logistic regression for overall response (= objective response + SD) of the different CpG dinucleotides measured. In the whole cohort, for all ten genes, the response rate to tamoxifen treatment was approximately 15 to 20% higher (odd ratios [OR's] ranging from 1.5 to 3.5) for patients whose tumours had a favourable DNA methylation status than those with an unfavourable status. In concordance, for the 10 genes, the median PFS in the former group of patients was on average 1.8 times longer than that in the latter group (hazard ratios (HR's) ranging from 0.54 to 0.77). Thus, also in the complete cohort, these 10 genes were associated with disease outcome after tamoxifen treatment.

Prediction of response to tamoxifen treatment in advanced breast cancer patients is based traditionally on the patient, disease, and tumour characteristics (Pyrhonen S, Ellmen J, Vuorinen J, Gershanovich M, Tominaga T, Kaufmann M, Hayes DF. Meta-analysis of trials comparing toremifene with tamoxifen and factors predicting outcome of antiestrogen therapy in postmenopausal women with breast cancer. Breast Cancer Res Treat. 1999 ;56(2):133-43), i.e., age, first dominant site of relapse, disease-free interval, and ER status. We compared a predictive score calculated with the multivariable estimates of the traditional predictive

factors (traditional factors-based score) with a score derived from DNA methylation data only (DNA methylation-based score). For a DNA methylation-based score, we included only genes whose DNA methylation status predicted response independent of each other. To establish this, we added the DNA methylation status information of each of the 10 genes simultaneously to a multivariable logistic regression model. After backward elimination of the non-significant genes ( $P < 0.05$ ), five genes, *i.e.* phosphoserine amino transferase (PSA-T), stathmin (STMN1), S100 protein A2 (S100A2), transforming growth factor  $\beta$  receptor II (TGFB2), and glutamate receptor 2D (GRIN2D), were statistically significant and predicted response, independent of one another. The DNA methylation-based score that was subsequently compared to the traditional factors-based score was derived from the multivariable estimates of these five genes.

The score for each tumour based on either traditional predictive factors or DNA methylation status was used to divide the patients into 4 groups by its 25th, 50th, and 75th percentile values (Table 3). The DNA methylation-based score showed a much better discriminatory strength with overall response than the traditional factors-based score (Table 3). The overall response rates in the DNA methylation-based score increased from 26% for the patients in the first quarter (q1) (OR set at 1.0), 34% for in the second quarter (q2) (OR=1.5), 66% in third for q3 (OR=5.5) and 82% and last quarter for q4 (OR=13.0) ( $P < 0.001$ ) while for the traditional factors-based score the rates increased only from 36% (OR, set at 1.0) for q1 of this score, via 46% (OR=1.5) (q2) to 64% (OR=3.2) and 62% (OR=2.9) (q3) (q4), respectively ( $P = 0.013$ ) (Table 3).

Similarly, median PFS in the extreme quarters for the DNA methylation-based score differed 4.2 times (from 3.8 to 16.1 months) while for the traditional factors-based score the difference between the two extreme quarters was only half of that (2.1 times; from 4.7 to 9.7 months) (compare curves of Fig. 5A with Fig. 5B).

Hence, we have shown for the first time that an epigenetic profile based on the CpG island DNA methylation status of promoter regions of just five genes can predict the likelihood of therapy response in patients with ER-positive advanced breast cancer treated with tamoxifen therapy. Furthermore, it appeared that this prediction was much more accurate than the prediction based on commonly used traditional predictive factors, suggesting that DNA methylation analysis may be useful for clinical therapy decisions. Epigenetic profiling of

tumour tissue DNA can therefore be a competitive and simple alternative for tedious mRNA profiling that is highly dependent on well-preserved tumour tissue material. Besides that epigenetic DNA profiles are very stable, are localised to specific sites (the promoter region of a gene) and can be easily amplified by PCR. Above and beyond, DNA methylation status determination can be performed on archived frozen or easily accessible paraffin-embedded tumour tissue material, making it widely applicable in the routine clinical setting.

Table 1: Genes amplified according to Example 1.

Table 3. Predictive score for response<sup>a</sup>.

Factor	<i>n</i>	<i>P</i>	OR <sup>b</sup>	(95% CI) <sup>c</sup>
Traditional factors-based score <sup>d</sup> , ( $\chi^2=10.9$ , 3 degrees of freedom)				

q1	50	0.013	1	
q2	50		1.51	(0.68-3.38)
q3	50		3.16	(1.40-7.15)
q4	50		2.90	(1.29-6.53)

Methylation-based score<sup>e</sup>, ( $\chi^2=44.3$ , 3 degrees of freedom)

q1	50	<0.001	1	
q2	50		1.47	(0.62-3.47)
q3	50		5.52	(2.34-13.1)
q4	50		13.0	(4.97-33.8)

<sup>a</sup>, Logistic regression was used to test the strength of a relationship of a factor with the type of response to tamoxifen treatment; <sup>b</sup>, Odds ratio; <sup>c</sup>, 95% confidence interval; <sup>d</sup>, Score based on multivariable analysis of the traditional factors age (>70 yr, 55-70 yr, 41-55 yr versus ≤40 yr) dominant site of relapse (relapse to viscera or bone versus soft tissue), disease-free interval (>12 months versus ≤ 12 months), and log ER values. The score was divided into groups (q1 - q4) based on the 25<sup>th</sup>, 50<sup>th</sup> and 75<sup>th</sup> percentile values; <sup>e</sup>, Score based on the DNA methylation status of the 5 independent predicting genes PSA-T, STMN1, GRIN2D, TGFBR2 and S100A2. The score was divided into groups, q1 - q4, same as for the traditional factors-based score.

## Claims

1. A method for predicting the responsiveness of a subject with a cell proliferative disorder of the breast tissues to a therapy comprising one or more drugs which target the estrogen receptor pathway or are involved in estrogen metabolism, production, or secretion, said method comprising analysing the methylation pattern of a target nucleic acid comprising one or a combination of the genes taken from the group consisting of PSA, STMN1, S100A2, SFN, PRKCD, SYK, VTN, GRIN2D, TGFBR2 and COX7A2L and/or their regulatory regions by contacting at least one of said target nucleic acids in a biological sample obtained from said subject prior to or during treatment with the above mentioned substances.
2. A method according to Claim 1, wherein said target nucleic acid or acids comprise essentially one or more sequences from the group consisting of SEQ ID NOs: 27, 90, 41, 40, 121, 78, 115, 86, 43 and 105 and sequences complementary thereto.
3. A method according to Claims 1 or 2, wherein said cell proliferative disorder of the breast tissue is selected from the group consisting of ductal carcinoma *in situ*, lobular carcinoma, colloid carcinoma, tubular carcinoma, medullary carcinoma, metaplastic carcinoma, intraductal carcinoma *in situ*, lobular carcinoma *in situ* and papillary carcinoma *in situ*.
4. A method according to Claims 1 to 3, wherein said subjects are estrogen and/or progesterone receptor positive.
5. A method according to Claims 1 to 4, wherein said endocrine therapy is for the treatment of a relapse or metastatic cell proliferative disorder of the breast tissues.
6. A method according to claim 5, wherein said subjects have received chemotherapy.
7. A method according to claim 6, wherein said subjects did not receive chemotherapy.

8. A nucleic acid molecule consisting essentially of a sequence at least 18 bases in length according to one of the sequences taken from the group consisting of SEQ ID NOs: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587 and sequences complementary thereto.
9. An oligomer, in particular an oligonucleotide or peptide nucleic acid (PNA)-oligomer, said oligomer consisting essentially of at least one base sequence having a length of at least 10 nucleotides which hybridises to or is identical to one of the nucleic acid sequences according to SEQ ID NO: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587.
10. The oligomer as recited in Claim 9, wherein the base sequence includes at least one CpG dinucleotide.
11. The oligomer as recited in Claim 10, characterised in that the cytosine of the CpG dinucleotide is located approximately in the middle third of the oligomer.
12. A set of oligomers, comprising at least two oligomers according to any of claims 9 to 11.
13. A set of oligomers as recited in Claim 12, comprising oligomers for detecting the methylation state of all CpG dinucleotides within the group of SEQ ID NO: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587 and sequences complementary thereto.
14. A set of at least two oligonucleotides as recited in one of Claims 9 through 13, which is used as primer oligonucleotides for the amplification of nucleic acid sequences of one of SEQ ID NO: 188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586 and 587 and sequences complementary thereto.

15. A set of oligonucleotides as recited in one of Claims 9 through 13, characterised in that at least one oligonucleotide is bound to a solid phase.
16. Use of a set of oligonucleotides comprising at least three of the oligomers according to any of claims 9 through 15 for detecting the cytosine methylation state and/or single nucleotide polymorphisms (SNPs) within the sequences taken from the group SEQ ID NOs:188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586, 587 and sequences complementary thereto.
17. A method for manufacturing an arrangement of different oligomers (array) fixed to a carrier material for predicting breast cell proliferative disorders' response to tamoxifen treatment by analysis of the methylation state of any of the CpG dinucleotides of the group SEQ ID NOs:188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586, 587, wherein at least one oligomer according to any of the claims 9 through 15 is coupled to a solid phase.
18. An arrangement of different oligomers (array) obtainable according to claim 16.
19. An array of different oligonucleotide- and/or PNA-oligomer sequences as recited in Claim 18, characterised in that said oligonucleotides are arranged on a plane solid phase in the form of a rectangular or hexagonal lattice.
20. The array as recited in any of the Claims 18 or 19, characterised in that the solid phase surface is composed of silicon, glass, polystyrene, aluminium, steel, iron, copper, nickel, silver, or gold.
21. A DNA- and/or PNA-array for predicting breast cell proliferative disorders' response to a therapy comprising one or more drugs which target the estrogen receptor pathway or are involved in estrogen metabolism, production, or secretion by analysis of the methylation state of any of the CpG dinucleotides of the group SEQ ID NOs:188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364,

365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586, 587 comprising at least one nucleic acid according to one of the preceding claims.

22. A method according to any one of Claims 1 to 3 comprising the following steps:

- a) obtaining a biological sample containing genomic DNA,
- b) extracting the genomic DNA,
- c) converting cytosine bases in the genomic DNA sample which are unmethylated at the 5-position, to uracil or another base which is dissimilar to cytosine in terms of base pairing behavior;
- d) amplifying at least one fragment of the pretreated genomic DNA, wherein said fragments comprise one or more sequences selected from the group consisting of SEQ ID NO:188, 189, 430, 431, 314, 315, 542, 543, 214-217, 456-459, 556, 557, 376, 377, 618, 619, 364, 365, 606, 607, 306, 307, 548, 549, 220, 221, 462, 463, 344, 345, 586, 587 and sequences complementary thereto, and
- e) determining the methylation status of one or more genomic CpG dinucleotides by analysis of the amplificate nucleic acids.

23. The method according to Claim 22, characterised in that Step e) is carried out by means of hybridisation of at least one oligonucleotide according to SEQ ID NO: 1816-1833, 1114-1129, 1808-1815, 1762-1769, 1552-1559, 1490-1499, 1138-1147 and 1686-1693

24. The method as recited in Claim 22, characterised in that Step e) is carried out by means of hybridisation of at least one oligonucleotide according to Claims 9 through 15.

25. The method as recited in Claim 22, characterised in that Step e) is carried out by means of hybridisation of at least one oligonucleotide according to Claims 9 through 15 and extension of said hybridised oligonucleotide(s) by means of at least one nucleotide base.

26. The method as recited in Claim 22, characterised in that Step e) is carried out by means of sequencing.

27. The method as recited in Claim 22, characterised in that Step d) is carried out using methylation specific primers.

28. The method as recited in Claim 22, characterised in that Step e) is carried out by means of a combination of at least two of the methods described in Claims 23 through 27.

29. The method as recited in Claim 22, characterised in that the treatment is carried out by means of a solution of a bisulfite, hydrogen sulfite or disulfite.

30. A method according to any one of Claims 1 to 3 comprising the following steps:

a) obtaining a biological sample containing genomic DNA,

b) extracting the genomic DNA,

c) digesting the genomic DNA comprising one or more of the sequences from the group consisting of SEQ ID NOs 27, 90, 41, 40, 121, 78, 115, 86, 43 and 105 and sequences complementary thereto with one or more methylation sensitive restriction enzymes, and

d) determining of the DNA fragments generated in the digest of step c).

31. The method according to Claim 30, characterised in that the target sequence or sequences digested in Step c) comprises one or more sequences from the group consisting of SEQ ID NO 27, 90, 41, 40, 121, 78, 115, 86, 43 and 105.

32. A method according to one of Claims 30 or 31, wherein the DNA digest is amplified prior to step d).

33. The method as recited in one of Claims 22 through 29 and 32 characterised in that more than six different fragments having a length of 100 - 200 base pairs are amplified.

34. The method as recited in one of Claims 22 through 29, 32 and 33 characterised in that the amplification of several DNA segments is carried out in one reaction vessel.

17-14-03

35. The method as recited in one of the Claims 22 through 29 and 32 through 34, characterised in that the polymerase is a heat-resistant DNA polymerase.
- 5 36. The method as recited in one of the Claims 22 through 29 and 32 through 35, characterised in that the amplification is carried out by means of the polymerase chain reaction (PCR).
- 10 37. The method as recited in one of the 22 through 29 and 32 through 36, characterised in that the amplicates carry detectable labels.
38. The method according to Claim 37 wherein said labels are fluorescence labels, radionuclides and/or detachable molecule fragments having a typical mass which can be detected in a mass spectrometer.
- 15 39. The method as recited in one of the Claims 22 through 29, characterised in that the amplicates or fragments of the amplicates are detected in the mass spectrometer.
- 20 40. The method as recited in one of the Claims 38 and/or 39, characterised in that the produced fragments have a single positive or negative net charge for better detectability in the mass spectrometer.
- 25 41. The method as recited in one of Claims 37 through 40, characterised in that detection is carried out and visualised by means of matrix assisted laser desorption/ionization mass spectrometry (MALDI) or using electron spray mass spectrometry (ESI).
- 30 42. The method as recited in one of the Claims 22 through 37, characterised in that the genomic DNA is obtained from cells or cellular components which contain DNA, sources of DNA comprising, for example, cell lines, histological slides, biopsies, tissue embedded in paraffin, breast tissues, blood, plasma, lymphatic fluid, lymphatic tissue, duct cells, ductal lavage fluid, nipple aspiration fluid, bone marrow and combinations thereof.
43. A kit comprising a bisulfite (= disulfite, hydrogen sulfite) reagent as well as oligonucleotides and/or PNA-oligomers according to one of the Claims 9 through 15.

17-04-03

44. A kit according to claim 43, further comprising standard reagents for performing a methylation assay from the group consisting of MS-SNuPE, MSP, Methyl light, Heavy Methyl, nucleic acid sequencing and combinations thereof.

5

45. The use of a method according to one of claims 1 through 7, 17, and 20 to 42, a nucleic acid according to Claim 8, of an oligonucleotide or PNA-oligomer according to one of the Claims 9 through 15, of a kit according to Claim 43 or 44, of an array according to one of the Claims 19 through 21 or of a set of oligonucleotides according to one of claims 12 through 15 for the treatment, characterisation, classification and/or differentiation, of breast cell proliferative disorders.

10

E30111

**Abstract**

5 The present invention relates to modified and genomic sequences, to oligonucleotides and/or PNA-oligomers for detecting the cytosine methylation state of genomic DNA, as well as to a method for predicting the response of a subject with a cell proliferative disorder of the breast tissues, to endocrine treatment.
